## 6.1 MULTIPLEXING

Whenever the bandwidth of a medium linking two devices is greater than the link can be shared. Multiplexing is the set of the link can be shared. Whenever the bandwidth of a medium width needs of the devices, the link can be shared. Multiplexing is the set of the width needs of the devices, the link can be shared. Multiplexing is the set of t width needs of the devices, the link can be simultaneous transmission of multiple signals across a single data that allow the simultaneous transmission of multiple signals across a single data that allow the simultaneous transmission of multiple signals across a single data that allow the simultaneous transmission of multiple signals across a single data that allow the simultaneous transmission of multiple signals across a single data that allow the simultaneous transmission of multiple signals across a single data that allow the simultaneous transmission of multiple signals across a single data that allow the simultaneous transmission of multiple signals across a single data that allow the simultaneous transmission of multiple signals across a single data that allow the simultaneous transmission of multiple signals across a single data that allow the simultaneous transmission of multiple signals across a single data that allow the simultaneous transmission of multiple signals across a single data that allow the simultaneous transmission of multiple signals across a single data that the simultaneous transmission of multiple signals across a single data that the simultaneous transmission of multiple signals across a single data that the simultaneous transmission of multiple signals across a single data that the simultaneous transmission of multiple signals across a single data that the simultaneous transmission of multiple signals across a single data that the simultaneous transmission of multiple signals across a single data that the simultaneous transmission of multiple signals across a single data that the simultaneous transmission of multiple signals across a single data that the simultaneous transmission of multiple signals across a single data that the simultaneous transmission of multiple signals across a single data that the signal across a single data that the signal across a single data that the signal across a single data that the signals across a single data that the signal across a single data that that allow the simultaneous transmission of the simultaneous trans As data and telecommunications use means this increase by continuing to add individual links each time a new channel is her handwidth links and use each to carry multiple sin this increase by continuing to add many or we can install higher-bandwidth links and use each to carry multiple signal today's technology includes high-bandwidth mediant or we can install higher-bandwidth microwaves. Each has a bandwidth media and satellite microwaves. Each has a bandwidth media optical fiber and terrestrial and satellite microwaves. Each has a bandwidth optical fiber and terrestrial are average transmission signal. If the bandwidth is optical fiber and terrestrial and success of that needed for the average transmission signal. If the bandwidth of a because of the devices connected to it, the bandwidth of a because of the devices connected to it, the bandwidth of a because of the devices connected to it, the bandwidth of a because of the devices connected to it, the bandwidth of a because of the devices connected to it, the bandwidth of a because of the devices connected to it, the bandwidth of a because of the devices connected to it. greater than the bandwidth needs of the devices connected to it, the bandwidth needs of all resources be and the bandwidth needs of the devices connected to it, the bandwidth needs of the devices connected to it, the bandwidth needs of the devices connected to it, the bandwidth needs of the devices connected to it, the bandwidth needs of the devices connected to it, the bandwidth needs of the devices connected to it, the bandwidth needs of the devices connected to it, the bandwidth needs of the devices connected to it, the bandwidth needs of the devices connected to it, the bandwidth needs of the devices connected to it, the bandwidth needs of the devices connected to it, the bandwidth needs of the devices connected to it, the bandwidth needs of the devices connected to it, the bandwidth needs of the devices connected to it, the bandwidth needs of the devices connected to it. is wasted. An efficient system maximizes the utilization of all resources; bandwin one of the most precious resources we have in data communications.

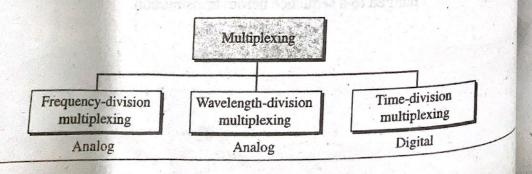

In a multiplexed system, n lines share the bandwidth of one link. Figure 6.1 the basic format of a multiplexed system. The lines on the left direct their transmission as single street them into a single street them. streams to a multiplexer (MUX), which combines them into a single stream (many) one). At the receiving end, that stream is fed into a demultiplexer (DEMUX), which is the receiving end, that stream is fed into a demultiplexer (DEMUX), which is the receiving end, that stream is fed into a demultiplexer (DEMUX), which is the receiving end, that stream is fed into a demultiplexer (DEMUX), which is the receiving end, that stream is fed into a demultiplexer (DEMUX), which is the receiving end, that stream is fed into a demultiplexer (DEMUX), which is the receiving end, that stream is fed into a demultiplexer (DEMUX), which is the receiving end, that stream is fed into a demultiplexer (DEMUX), which is the receiving end, that stream is fed into a demultiplexer (DEMUX), which is the receiving end, that stream is fed into a demultiplexer (DEMUX), which is the receiving end, the receiving end in the recei separates the stream back into its component transmissions (one-to-many) directs them to their corresponding lines. In the figure, the word link refers to physical path. The word channel refers to the portion of a link that carries a training sion between a given pair of lines. One link can have many (n) channels.

Dividing a link into channels Figure 6.1

There are three basic multiplexing techniques: frequency-division multiplexing wavelength-division multiplexing, and time-division multiplexing. The first two 11 techniques designed for analog signals, the third, for digital signals (see Figure 6.2)

Figure 6.2 Categories of multiplexing

Although some textbooks consider carrier division multiple access (CDMA) as a fourth multiplexing category, we discuss CDMA as an access method (see Chapter 12).

### Frequency-Division Multiplexing 6.1.1

Frequency-division multiplexing (FDM) is an analog technique that can be applied when the bandwidth of a link (in hertz) is greater than the combined bandwidths of the signals to be transmitted. In FDM, signals generated by each sending device modulate different carrier frequencies. These modulated signals are then combined into a single composite signal that can be transported by the link. Carrier frequencies are separated by sufficient bandwidth to accommodate the modulated signal. These bandwidth ranges are the channels through which the various signals travel. Channels can be separated by strips of unused bandwidth—guard bands—to prevent signals from overlapping. In addition, carrier frequencies must not interfere with the original data frequencies.

Figure 6.3 gives a conceptual view of FDM. In this illustration, the transmission path is divided into three parts, each representing a channel that carries one transmission.

Figure 6.3 D E M U Channel 1 Output MU Imput Channel 2 lines lines Channel 3

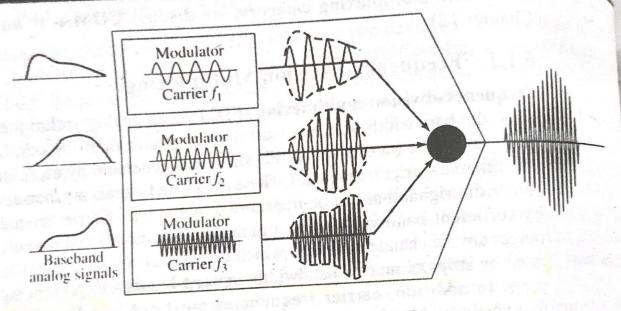

Frequency-division multiplexing

We consider FDM to be an analog multiplexing technique; however, this does not mean that FDM cannot be used to combine sources sending digital signals. A digital signal can be converted to an analog signal (with the techniques discussed in Chapter 5) before FDM is used to multiplex them.

FDM is an analog multiplexing technique that combines analog signals.

Figure 6.4 is a conceptual illustration of the multiplexing process. Each source generates a signal of a similar frequency range. Inside the multiplexer, these similar signals modulate different carrier frequencies  $(f_1, f_2, \text{ and } f_3)$ . The resulting modulated signals are then combined into a single composite signal that is sent out over a media link that has enough bandwidth to accommodate it.

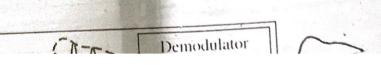

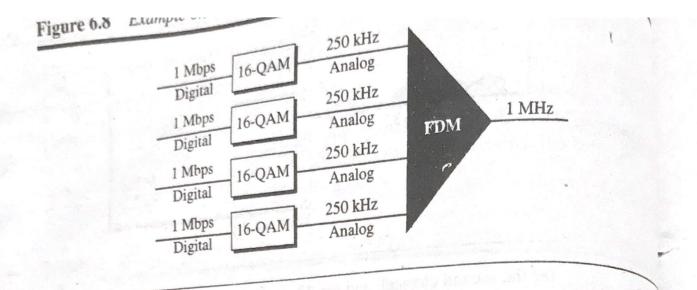

## Demultiplexing Process

The demultiplexer uses a series of filters to decompose the multiplexed signal into a constituent component signals. The individual signals are then passed to a demodular that separates them from their carriers and passes them to the output lines. Figure 65% a conceptual illustration of demultiplexing process.

FDM demultiplexing example Figure 6.5

# The Analog Carrier System

To maximize the efficiency of their infrastructure, telephone companies have tradition To maximize the efficiency of died into formation ally multiplexed signals from lower-bandwidth lines, into formation for the formation of the ally multiplexed signals from to the combined into fewer but bigger characters way, many switched or leased lines can be combined into fewer but bigger characters. nels. For analog lines, FDM is used.

One of these hierarchical systems used by telephone companies is made up groups, supergroups, master groups, and jumbo groups (see Figure 6.9).

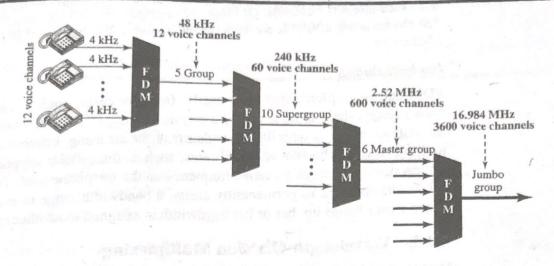

In this analog hierarchy, 12 voice channels are multiplexed onto a higher-bandwidth line to create a group. A group has 48 kHz of bandwidth and supports 12 voice channels

At the next level, up to five groups can be multiplexed to create a composite signal called a supergroup. A supergroup has a bandwidth of 240 kHz and supports up to 60 voice channels. Supergroups can be made up of either five groups or 60 independent voice channels.

At the next level, 10 supergroups are multiplexed to create a master group. A master group must have 2.40 MHz of bandwidth, but the need for guard bands between the supergroups increases the necessary bandwidth to 2.52 MHz. Master groups support up to 600 voice channels.

Finally, six master groups can be combined into a jumbo group. A jumbo group must have 15.12 MHz ( $6 \times 2.52$  MHz) but is augmented to 16.984 MHz to allow for guard bands between the master groups.

Figure 6.9 Analog hierarchy

### Other, Applications of FDM

A very common application of FDM is AM and FM radio broadcasting. Radio uses the air as the transmission medium. A special band from 530 to 1700 kHz is assigned to AM radio. All radio stations need to share this band. As discussed in Chapter 5, each AM station needs 10 kHz of bandwidth. Each station uses a different carrier frequency, which means it is shifting its signal and multiplexing. The signal that goes to the air is a combination of signals. A receiver receives all these signals, but filters (by tuning) only the one which is desired. Without multiplexing, only one AM station could broadcast to the common link, the air. However, we need to know that there is no physical multiplexer or demultiplexer here. As we will see in Chapter 12, multiplexing is done at the data-link layer.

The situation is similar in FM broadcasting. However, FM has a wider band of 88 to 108 MHz because each station needs a bandwidth of 200 kHz.

Another common use of FDM is in television broadcasting. Each TV channel has its own bandwidth of 6 MHz.

The first generation of cellular telephones (See Chapter 16) also uses FDM. Each user is assigned two 30-kHz channels, one for sending voice and the other for receiving. The voice signal, which has a bandwidth of 3 kHz (from 300 to 3300 Hz), is modulated by using FM. Remember that an FM signal has a bandwidth 10 times that of the modulating signal, which means each channel has 30 kHz ( $10 \times 3$ ) of bandwidth. Therefore, each user is given, by the base station, a 60-kHz bandwidth in a range available at the time of the call.

### Example 6.4

The Advanced Mobile Phone System (AMPS) uses two bands. The first band of 824 to 849 MHz is used for sending, and 869 to 894 MHz is used for receiving. Each user has a bandwidth of 30 kHz in each direction. The 3-kHz voice is modulated using FM, creating 30 kHz of modulated signal. How many people can use their cellular phones simultaneously?

Solution

Each band is 25 MHz. If we divide 25 MHz by 30 kHz, we get 833.33. In reality, the band is 25 MHz. If we divide 25 MHz by 30 kHz, we get 833.33. In reality, the band is 25 MHz. If we divide 25 MHz by 30 kHz, we get 833.33. In reality, the band is 25 MHz. If we divide 25 MHz by 30 kHz, we get 833.33. In reality, the band is 25 MHz. If we divide 25 MHz by 30 kHz, we get 833.33. In reality, the band is 25 MHz. If we divide 25 MHz by 30 kHz, we get 833.33. In reality, the band is 25 MHz. If we divide 25 MHz by 30 kHz, we get 833.33. In reality, the band is 25 MHz. If we divide 25 MHz by 30 kHz, we get 833.33. In reality, the band is 25 MHz. If we divide 25 MHz by 30 kHz, we get 833.33. In reality, the band is 25 MHz. Each band is 25 MHz. If we divide 25 MHz by 30 kHz, which which the band is divided into 832 channels. Of these, 42 channels are used for control, which means is divided into 832 channels. Of these, 42 channels are used for control, which means is divided into 832 channels. is divided into 832 channels. Of these, 42 channels are a wailable for cellular phone users. We discuss AMPS in greater details

### Implementation

FDM can be implemented very easily. In many cases, such as radio and television represented the state of the FDM can be implemented very easily. In many broadcasting, there is no need for a physical multiplexer or demultiplexer. As long to the air using different carrier freeze broadcasting, there is no need for a physical and the stations agree to send their broadcasts to the air using different carrier frequencies the stations agree to send their broadcasts to the air using different carrier frequencies the stations agree to send their broadcasts to the air using different carrier frequencies multiplexing is achieved. In other cases, such as the cellular telephone system, a base multiplexing is achieved. There is not multiplexing is achieved. In other cases, such station needs to assign a carrier frequency to the telephone user. There is not enough station needs to assign a carrier frequency to bandwidth range to every telephone user bandwidth in a cell to permanently assign a bandwidth range to every telephone user When a user hangs up, her or his bandwidth is assigned to another caller.

# 6.1.2 Wavelength-Division Multiplexing

Wavelength-division multiplexing (WDM) is designed to use the high-data-rate capability of fiber-optic cable. The optical fiber data rate is higher than the data rate of metallic transmission cable, but using a fiber-optic cable for a single line wastes the available bandwidth. Multiplexing allows us to combine several lines into one.

WDM is conceptually the same as FDM, except that the multiplexing and demultiplexing involve optical signals transmitted through fiber-optic channels. The idea is the same: We are combining different signals of different frequencies. The difference

Figure 6.10 gives a conceptual view of a WDM multiplexer and demultiplexer. Very narrow bands of light from different sources are combined to make a wider band of light. At the receiver, the signals are separated by the demultiplexer.

Figure 6.10 Wavelength-division multiplexing
